What does the app do?

The Price File Builder takes price files from suppliers (CSV or Excel) and loads them into the RxOne database (**suppliers.mdb**). It handles the column matching, description tidying, and database update — all without any manual SQL.

The app remembers your settings for each supplier, so after the first time the work is much faster.

i The app has two modes at the top: **Price File** (for regular supplier price updates) and **Specials File** (for specials promotions). This guide covers the Price File mode.

Step-by-step: processing a price file

1 Select the supplier

Pick the supplier from the dropdown at the top right. The app will silently start loading their existing database records in the background — by the time you get to the preview step, it will already be ready.

2 Open the price file

Click **Open File** and browse to the supplier's CSV or Excel file. If the Excel file has more than one sheet, a window will ask you which sheet to use — pick the one with the product data.

3 Check the column mappings

On the right panel, check that the columns are mapped correctly (PLU, Pharmacode, Retail, Cost, etc.). For suppliers the app already knows, these will be pre-filled. If anything looks wrong, change the dropdowns to the correct columns from the file.

4 Check the TradeName settings

Scroll down the right panel to the TradeName section. Check which columns are being used to build the product description and whether title case and unit normalisation are turned on. Again, these will usually be set correctly for known suppliers.

5 Click Build Output

Click the **Build Output** button. The app processes the file, applies description rules, removes rows with no identifying code, and shows the processed rows. The row count is displayed at the bottom of the screen.
